JavaScript Equality Operators (== vs ===)

Loose Equality (==)

The **==** operator compares two values after performing **type coercion** if their data types are different. It checks whether the values are equal, not whether their data types are the same.

Examples

```
console.log(10 == "10"); // true
console.log(true == 1); // true
console.log(0 == false); // true
console.log(null == undefined); // true
```

Strict Equality (===)

The **===** operator compares both the **value** and the **data type**. It does not perform type coercion.

```
console.log(10 === "10"); // false
console.log(10 === 10); // true
```

Quick Difference

== → Compares values after type coercion.
=== → Compares both value and type without type coercion.

Interview Answer (30 seconds)

The **==** operator compares two values after type coercion if needed, while the **===** operator compares both value and data type without type coercion. For most cases, **===** is recommended because it avoids unexpected results.
